Overview

Description

This competition aims to regress the value of used cars using some simple factors affecting their value.

Evaluation

Description of data

The data consists of 70,000 training rows and 30,000 test rows. Each row has an id field. The rating factors in the X datasets are as follows:

- **brand** (categorical)
- **year** (numeric)
- **age** (numeric)
- **engine_size** (numeric)
- **power** (numeric)
- **mileage** (numeric)
- **prev_owners** (numeric)

The y_train dataset contains the corresponding valuations for each id in the X_train dataset. These can be used to train a model to predict value.

The aim is to predict the value of the cars represented by the rows in X_test. Submissions should consist of a two column csv with id and value as the columns.
